Wideband Vector Antenna for Dual-Polarized and 3-D Direction Finding Applications

Johan Duplouy*,†, Christophe Morlaas*, Hervé Aubert†, Senior Member, IEEE, Patrick Potier‡, and Philippe Pouliguen‡

Abstract—A wideband and radiation pattern reconfigurable vector antenna is proposed for dual-polarized and 3-D direction finding applications. Compared with the state of the art, this antenna achieves the accurate estimation of the direction of arrival of an incoming vertically- or horizontally-polarized electromagnetic field over a wider bandwidth (7:1). Measurement results are in good agreement with the simulated results obtained from full-wave electromagnetic simulations.

Index Terms—wideband magnetic and electric dipoles, Vivaldi antennas, vector sensor, direction-of-arrival antenna, dual-polarized antenna, reconfigurable antenna.

I. INTRODUCTION

DIRECTION Finding (DF) of incoming ElectroMagnetic (EM) fields has become very appealing in many civil and military applications related to radiolocation or radio-localization [1]. Most of the DF antennas operate over a wide frequency band and estimate the Direction-of-Arrival (DoA) of an incoming EM field over a 2-D angular coverage (i.e., only the azimuth angle is estimated for a restricted range of elevation angles). The DoA estimation relies usually on the spatial diversity of the antenna array [2]. However, there are applications that may require a 3-D angular coverage (i.e., estimation of both azimuth and elevation angles). This coverage can be achieved regardless of the polarization of the incident EM field through an innovative DF technique provided by a Vector Antenna (VA) [3]. Ideally, the VA enables the measurement of the six components of the incoming EM field (i.e., \( E_x \), \( E_y \), \( H_x \), \( H_y \), and \( H_z \) in the Cartesian coordinate system), allowing the DoA estimation across the 3-D space.

Many VAs have been reported over the last few years, including the active solution covering frequencies below 30 MHz [4] and the passive and dual-band solution operating at GSM frequencies [5]. Very recently, the authors proposed the first passive, wideband and radiation pattern (RP) reconfigurable VA [6]–[8], referred here to as the Two Season VA. The measured electrical characteristics of this antenna are detailed in [6], while its simulated and measured DF performances are reported in [7] and [8], respectively. As in [5], the Two Season VA is only able to estimate the DoA of vertically-polarized EM fields, since only three components can be measured \( (E_z, H_x, \text{and } H_y) \). The Two Season VA enables the accurate DoA estimation over a measured impedance bandwidth of 1.69:1 (or [2.10 GHz - 3.55 GHz]).

In this letter, a novel VA, referred here to as the Four Season VA, is proposed. Compared to the previous 4-port Two Season VA, this new VA enables the DoA estimation of an incoming EM field, whatever its polarization and over a wider bandwidth (7:1, or [1 GHz - 7 GHz]). These improved DF performances resulted from: (i) the modification of the VA feeding circuit, and (ii) the addition of the horizontal EM sensor. Moreover, despite the more complex feeding circuit (eight ports), it is shown that the accuracy of the DoA estimation of an incident vertically-polarized EM field is improved thanks to the measurement of the horizontal components \( (E_x, E_y \text{ and } H_z) \).

II. THE FOUR SEASON VECTOR ANTENNA

A. Design consideration

The Four Season VA consists of the Two Season VA (vertical part of the VA depicted in Fig. 1(a)) mounted over a 4-port circular array of eight Vivaldi antennas (see details in Fig. 1(c&d) and Table I). Compared with the Two Season VA, the Four Season VA is intended to estimate the DoA of incident horizontally-polarized EM fields in order to reduce the estimation errors due to polarization mismatch. This antenna allows the measurement of six EM field components. The idea is to replace the metallic support of the Two Season VA by eight additional radiating elements fed through four ports. These elements serve as a ground plane for the two vertical semi-circular arrays and as an EM sensor for measuring the three components \( H_z, E_x \text{ and } E_y \) (that could not be measured in [8]). More specifically, the horizontal circular array is the 1.5 scale-up replica of the semi-circular arrays of the Two Season VA. Moreover, the power splitter part of the feeding circuit of the Vivaldi antennas has been modified. Contrary to what is stated in [6], the input impedance of the Vivaldi antennas is about 100 \( \Omega \) (and not 65 \( \Omega \)) when antennas are connected within the array. Therefore, the 1:2 microstrip line power splitter used in [6], and fabricated using the T- junction and impedance transition lines (Fig. 1(f)), can be advantageously replaced by two 100 \( \Omega \) parallel microstrip...

B. Signal processing consideration

Following [6], the measurement of the EM field components $H_x$, $H_y$ and $E_z$ are performed from three sets of weighting coefficients assigned to the received signals at the VA vertical ports (denoted by the acronym RPC 0, which stands for Radiation Patterns Combination 0). According to the mirror symmetry between the two feeding circuits of the 2-port vertical array (Fig. 1(e)) along the $y$-axis (resp. $x$-axis), the component $H_x$ (resp., $H_y$) can be measured when ports 1 and 2 (resp., ports 3 and 4) are out of phase (i.e., by applying the weighting coefficients [1,-1,1,-1]) in order to excite in phase the four Vivaldi antennas to form a magnetic dipole. The component $E_z$ is measured by recombining the ports of the V A horizontal part (a horizontal plane (resp. $y$-plane) and an electric-wall along the $yz$-plane (resp. $xz$-plane) to form an electric dipole oriented along the $x$-axis (resp., $y$-axis). The weighting coefficients associated with the measurement of the six EM field components are summarized in Table II (RPC 00).

III. Simulated and Measured Electrical Performances

The electrical performances (impedance matching and radiation patterns) of the Four Season VA have been assessed using full-wave EM simulations (Ansys HFSS) and from measurements carried out in an anechoic chamber. A photograph of the prototype is given in Fig. 1(h).

A. Impedance matching and mutual coupling

The VSWR of the Four Season VA is shown in Fig. 2. The measured impedance bandwidth of the vertical and

horizontal radiating elements is of 6.77:1 (or [1.24 GHz - 8.40 GHz]) and 10.74:1 (or [0.79 GHz - 8.49 GHz]) for a VSWR $\leq 2.3$, respectively. As the horizontal circular array is the scale-up replica of the semi-circular array of the Two Season VA, there is approximately a factor 1.5 between the lower operating frequency of the vertical and horizontal radiating elements. Moreover, there is a good agreement between simulation and measurement results, even if the measured VSWR at the vertical ports is slightly degraded at high frequencies due to technological inaccuracies in the prototype manufacturing process. Hence, the impedance bandwidth of the prototype is limited to 6.77:1 (or [1.24 GHz - 8.47 GHz]) and 10.74:1 (or [0.79 GHz - 8.49 GHz]) for a half-sphere of radius $0.47\lambda_{124\text{GHz}}$. Besides, the radius of the horizontal circular array is $0.30\lambda_{0.79\text{GHz}}$, while the radius of the vertical semi-circular arrays is of $0.32\lambda_{124\text{GHz}}$. This corresponds approximately to a reduction by a factor 1.6 of the electrical size of the vertical part of the Two Season VA.

### B. Radiation patterns

The RPs of the Four Season VA associated with the measurement of the six components of an incoming EM field are depicted in Fig. 4. For symmetry reasons, the RPs associated with the measurement of $E_y$ and $H_y$ are not shown here. It can be observed that the RPs are similar to those of electric and magnetic dipoles in their respective E-plane and H-plane. As expected from Chu’s theory [9], some ripples appear in the RPs of the electric and magnetic dipoles as the frequency increases. However, there is an overall good agreement between the measured and the simulated RPs. Moreover, for some frequencies, the size of the horizontal antenna elements impacts the RP of the vertical antenna elements. For example, at 5 GHz in Fig. 4(g), the radiation level is reduced in the y-axis direction and more sidelobes appear. However, this RP modification does not impact the DoA estimation performance.

### IV. Simulated and Measured Direction Finding Performances

The DF performances of the Four Season VA have been evaluated in the 3-D upper half space using the MUSIC algorithm [10] and from full-wave EM simulation or measurement data. The accuracy of the DoA estimation is evaluated through the angular error $\Delta\text{RMS}$ between the estimated angles of arrival and the exact angles (see, e.g., Eq. (9) in the Appendix of [8] for the detailed definition), and its 95th percentile, which indicates the maximum error for 95% of all estimated DoAs. The estimation parameters are those given in [8], except that the DoA estimation is performed using the six components (instead of the three components) of the incoming EM field (RPC 00) from 1 GHz to 8.2 GHz with a 0.4 GHz frequency step. This incoming EM field is either vertically- or horizontally-polarized. Moreover, as described in [5], the calibration matrix derived from the simulated or measured RPs of the antenna is used for taking into account the eventual amplitude and phase distortions. Fig. 5 displays the 95th percentile of $\Delta\text{RMS}$ for an incoming vertically- or horizontally-polarized EM field. For comparison purpose, the DoA estimation accuracy of a vertically-polarized incident EM field obtained from using only RPC 0 (that is, from only the measurement of the three field components $H_x$, $H_y$ and $E_z$) is also depicted. It can be observed that the additional measurement of the field components $E_x$, $E_y$ and $H_z$ improves the DoA estimation of the vertically-polarized EM field in terms of accuracy and frequency coverage. The measured 95th percentile of $\Delta\text{RMS}$ does actually not exceed 5° from 1 GHz up to approximately 7.0 GHz. Moreover, the DoA estimation of the horizontally-polarized EM field is also very accurate, since the measured 95th percentile of $\Delta\text{RMS}$ is smaller than 2° up to 8.2 GHz. In addition, there is a good agreement obtained between the simulated and measured results. Fig. 6 displays the measured angular distance $\Delta\text{RMS}$ achieved from the Four Season VA at the central frequency (3.8 GHz) using
RPC 0 or RPC 00 in the DoA estimation process. It can be observed that using RPC 00 instead of RPC 0 enhances the accuracy of the DoA estimation of the vertically-polarized EM field in the angular area in which the estimation errors were maximum. Furthermore, the $\Delta \theta_{\text{RMS}}$ does not exceed 5° in every direction of the 3-D upper half space for both polarizations of the incoming EM field when RPC 00 is used. Finally, these results confirm that the Four Season VA can be used for dual-polarized and 3-D DF applications with a very good DoA estimation accuracy over a 7:1 bandwidth (or [1 GHz - 7 GHz]).

**V. Conclusion**

A wideband VA for dual-polarized and 3-D DF application has been presented in this letter. The measurement of the six components of the vertically- or horizontally-polarized incoming EM field is performed from the RP reconfigurability of two orthogonal and collocated semi-circular arrays mounted over a circular array of Vivaldi antennas. Such VA enables the accurate estimation of the DoA across the 3-D upper half space and over a wide bandwidth (7:1). The measurement results have confirmed the simulated performances. Future works will be focused on improving the DF performances of this VA in electromagnetic reverberant and/or multi-source environments, and reducing the antenna size.
